# Exceptional weather events 

Type of event:
Rainfall / flooding

Date:
November 2002

# Precipitation event around $14^{\text {th }}$ November 2002. 

(draft 25 November 2002)

There is a suspicion that heavy rainfall events have been increasing in frequency in recent years. Increases in rainfall during the winter half of the year have been reported from a number of countries. This is consistent with what might be expected in a global warming scenario - in particular, many climate model scenarios indicate increases in rainfall over parts of Europe apart from Mediterranean regions (IPCC, 2001). Though more work needs to be done, there is some indication that the intensity of short duration rainfall may be increasing in Ireland (Kiely 1999,Sheridan 2001).

One of the recent flooding events in Ireland affected Dublin in November 2002 and caused significant disruption and damage, especially in the area of the lower Tolka catchment. The rainfall event lasted from 1900 on $13^{\text {th }}$ to 0800 on $15^{\text {th }}$. The following is an attempt to put the event in context.

Comments here refer mainly to the period available in our database. The start dates for database data are 1941 Glasnevin, 1944 Dublin Airport, 1954 Casement Aerodrome.

## The Event

## Preceding days:

October 2002 was generally a very wet month in the area (Appendix II). Rainfall was 181 mm at Dublin Airport (second highest monthly accumulation on record for any month there). At Casement it was the wettest month on record at 178.9 mm . At 161.1 at Glasnevin (Botanic Gardens) it was the second wettest October (sixth wettest month) in the database records (Appendix III).
November also started wet with about 50 mm being measured up to the morning of the $13^{\text {th }}$ compared to a normal November total of about 65 mm . The event in question brought the total for first half of November well above the normal total for the whole month. Soil moisture deficit calculations indicate that the ground was well saturated (see appendix I).

## Met Éireann - The Irish Meteorological Service

## 13-15 November 2002

## Rainfall on $13^{\text {th }}$ to $15{ }^{\text {th }}$ November

The graph shows the hourly falls at a selection of stations during the event (left axis), the average falls at these stations and the total accumulation for this average (right hand axis). Water levels in the river Tolka (Botanic Gardens) started to rise late on $13^{\text {th }}$, peaked initially at 1930 on $14^{\text {th }}$ (four to five hours after the rainfall peak) and rose subsequently by a further 0.23 m to the overall peak at 0145 on $15^{\text {th }}$ (Mac Carthaigh, 2002, see http://www.epa.ie/Press\ Releases/default.htm)

The following table gives an indication of the maximum falls of specific durations surpassing certain thresholds for on $13^{\text {th }}$ to $15^{\text {th }}$, extracted from chart recorders

| $\quad$Station <br> Duration | Casement | Glasnevin | Phoenix Park |
| :--- | ---: | ---: | ---: |
| 15 min |  | 5.8 |  |
| 30 |  | 10.3 |  |
| 60 | 8.3 | 15.5 | 15.8 |
| 2 hours | 12.0 | 17.5 | 23.4 |
| 3 | 15.6 | 20.1 | 25.4 |
| 4 | 19.5 | 22.9 | 29.7 |
| 6 | 21.5 | 26.2 | 33.2 |
| 12 | 36.5 | 37.0 | 50.1 |
| 24 | 58.6 | 61.3 | 76.2 |

During this period an average total of about 80 mm fell in the Dublin area (87.5 in the Phoenix Park, 85.4 in Dublin Airport, 74.7 in Glasnevin and 72.1 mm at Casement Aerodrome).
Observed 14 November 2002 (00-24)
Dublin Airport $\quad 74.6 \mathrm{~mm}$
Casement 52.5

## Radar

During the night of $13-14^{\text {th }}$, there was a large area of rainfall with the most intense parts over the Irish Sea and a sharp western edge. It was circulating cyclonically around a point somewhere to the between Wexford and Land's end. While the individual radar images through the day seemed to show the rain moving south over the west of Ireland, the line of most intense rainfall seemed to pivot about the Dublin area.

It should be noted that quantitative rainfall estimation from weather radar has large margins of error and the very close proximity to the radar at Dublin Airport may cause some further problems in quantitative estimation over Dublin city.

24-Hour radar precipitation accumulation
The 24 hour Dublin radar accumulation from 00 on $14^{\text {th }}$ showed a large area of 16 to 32 mm accumulation centred approximately on Dublin with the most intense ( 48 to 64 mm ) area centred on a small area (c 3 km radius) located about 12 km from the radar, bearing about 250 degrees.

6-Hour radar precipitation accumulation
The midnight to 0600 radar accumulation (see Appendix V) showed a number of 16 to 32 mm pixels within 25 km of the radar location, mainly in the northwestern sector. The more intense rainfall on the 0600 to 1200 image appears to the west of the radar with a number of 16 to 32 mm pixels between 15 and 30 km distant from the radar bearing about 260 degrees. The largest number of pixels of this value were in the 1200 to 1800 accumulation in the sector between 180 and 280 degrees from the Airport clustered mostly around 10 km and 25 km distant.
The 1800 - 2400 image shows the rainfall area to have significantly contracted with only a very few 16 to 32 mm pixels remaining.

## Context

While hourly rainfalls are reported from some stations and can be extracted from charts for others, almost all rainfall stations report daily rainfall (measured at 0900 and assigned to previous day). On the basis of these 0900 to 0900 rainfalls, the $14^{\text {th }}$ November was the seventh / tenth / eighth wettest day on record at Dublin Airport, Casement Aerodrome and Glasnevin respectively (Appendix IV). Interestingly, in the case of all three stations, the rainfall on $20^{\text {th }}$ October 2002 was actually higher than that of the current event.

As mentioned before, the data presented here is from the electronically held records. In the case of Glasnevin where some data is available back to 1860, for example, we have paper records indicating daily falls on 25/8/1905 of 90.9 mm , on $3 / 9 / 1931$ of 77.5 mm and on $27 / 10 / 1880$ of 75.7 mm

## Return periods

For the Dublin area, north of the Liffey, the following ranges (mm) are calculated:

| Return period | 20 years | 50 years | 100 years |
| :--- | :--- | :--- | :--- |
| 12 hour duration | $53-57 \mathrm{~mm}$ | $64-69 \mathrm{~mm}$ | $72-78 \mathrm{~mm}$ |
| 24 hour duration | $63-68 \mathrm{~mm}$ | $76-82 \mathrm{~mm}$ | $87-93 \mathrm{~mm}$ |

For comparison, the maximum 12- and 24-hour (end time) falls for Dublin area for the event under consideration were

| Location | Airport | Casement | Phoenix | Glasnevin |
| :--- | :--- | :--- | :--- | :--- |
| 12 hour | $39.6(150100)$ | $36.5(150200)$ | $50.1(150200)$ | $37.0(141800)$ |
| 24 hour | $74.6(150000)$ | $58.6(150100)$ | $76.2(150100)$ | $61.3(142100)$ |

From this perspective, the 12-hour return observed rainfalls are not dramatically exceptional - return periods less than 20 years. The 24 -hour rainfalls are somewhat more significant ( 15 to 45 years approximately).
T. Sheridan

## Appendix V

Six hourly radar precipitation accumulations

Flooding follows heavy rain in east and south

Late on the 13th, an area of heavy rain moved into eastern areas, associated with a deep depression of 966 hPa which became slow-moving over the Irish Sea (see satellite image below left). Rain continued for over 30 hours in the Dublin area and was heavy at times, causing some severe flooding, especially along the valley of the River Tolka. The graph below shows the hourly falls at a selection of stations during the event (left hand axis), the average falls at these stations and the total accumulation for this average (right axis). After a period of very wet weather extending back to October, soil moisture levels in the area were already near saturation, so that almost all of the rain that fell was immediately discharged into water courses. Water levels measured on the Tolka at Glasnevin (Botanic Gardens) started to rise late on the 13th, peaked initially at 1930 on the 14th (four to five hours after the rainfall peak) and rose subsequently by a further 0.23 m to the overall peak of 2.42 m at 0145 on the 15 th, corresponding to a flowrate of $97 \mathrm{~m}^{3} / \mathrm{s}$. This was the highest level recorded in over 50 years at the station, including the major flood of December 1954 (Mac Cárthaigh, see www.epa.ie/Press\ Releases/default.htm).

As shown by the map on the left, between 60 and 100 mm of rain fell over a 48 -period in many eastern areas. Dublin Airport's daily fall of 75 mm up to midnight on the 14th was its highest for November since records began there in 1941; the only previous higher daily fall at the station was measured in June 1993.

Maximum 12-hour and 24-hour falls for Dublin stations over the period were as follows (date and time of ending in brackets):

|  | Dublin Apt | Casement | Phoenix Pk | Glasnevin |
| :--- | :--- | :--- | :--- | :--- |
| 12 hour | $39.6(150100)$ | $36.5(150200)$ | $50.1(150200)$ | $37.0(141800)$ |
| 24 hour | $74.6(150000)$ | $58.6(150100)$ | $76.2(150100)$ | $61.3(142100)$ |

These values compare with calculated return periods for north Dublin as follows:

| Return period | 20 years | 50 years | 100 years |
| :--- | :--- | :--- | :--- |
| 12 hour duration | $53-57 \mathrm{~mm}$ | $64-69 \mathrm{~mm}$ | $72-78 \mathrm{~mm}$ |
| 24 hour duration | $63-68 \mathrm{~mm}$ | $76-82 \mathrm{~mm}$ | $87-93 \mathrm{~mm}$ |

From this perspective, the 12 -hour observed rainfalls have a return period of less than 20 years, while 24 -hour falls are more significant, with 15 - to 45 -year returns.

Little or no rain fell over the south and southwest of the country during the 14th, but heavy falls on subsequent days brought flooding in these areas also, especially affecting Cork city. Cork Airport and Valentia Observatory measured over 120 mm in the 8 -day period between the 20 th and 27 th, or the equivalent of the normal total for all the month of November. Overall it was the wettest November on record at a number of stations; in consecutive months, Rosslare had both its wettest October and November since records began there in 1956. (satellite image courtesy Dundee University, pictures Peter Lennon)

Hourly rainfall at Dublin stations between
2000UTC on 13th and 1000UTC on 15th
